I am refurbishing a 250 that was my late father's amp. I am not too concerned with historical accuracy but more the functionality. Amp works, but unfortunately, someone stole the pedals when it was last used at a gig. (I hope(sarcasm)they made a small fortune selling them.) Now I am looking to build a 4-button replacement pedal and wah. After reading several posts here I am assuming the wah is a standard potentiometer pedal with a 10 k ohm pot in it? The four button pedal sounds simple enough to construct if I had the schematics. Also, where could I buy one of those 6 pin connectors? Is it something standard that say radio shack or an electronics parts store would stock? Would an old Vox amp 6 pin connector work? Once I can test the effects, I am sure I will find more things to repair. Thanks for any and all help.

The K250-4 amp does not need the footswitch to operate the effects. All effects are controllable from the amp. email me at djt@chartermi.net for the schematic. The amp would use the 6 pin XLR plug and you might have to google switchcraft A6M. Peavey and Vox used a DIN plug rather than the XLR plug.
