Hi, I'm a newbie to this Forum and look forward to being a part of what seems to be a pretty good one!

I received a K200 bass amp for repair and since its been a very long time since i've worked on Solid State amps, I'm somewhat stuck on this repair. The original complaint is noise and popping which I have not yet observed. During my initial testing I've noticed that the negative side of the output is clipping way before the plus side. I've done all the preliminary troubleshooting and all voltages both the high rails and the ± 8 volts are on the money. I've tried to swap the 2 pairs of output transistors and clipped the diodes in the protection circuits and checked multiple resistor values to no avail. Am I looking at driver transistor replacement? Any ideas would be greatly appreciated.

Thanks

Kenny

Welcome to the place. While not rare, a model 6 is fairly unusual.

If you know that one half of the signal is reduced, I will assume that you have a scope to look at the waveforms in the power amp. A couple of weeks back we were discussing a very similar problem that turned out to be the protection circuit turning on too early on one side of the amp.

Tell us what has been done to this one in the past. Are the drivers and outputs original? I assume that both the +40 and -40 supplies are solid and clean.

If you haven't already done so, look up the schematics for your amp in the technical section, that way we can discuss with part numbers, etc. First check would be voltages on the power amp board.

Again, welcome.

Thanks for the quick response. Yeah all voltages are on the money and protection circuits disabled by clipping one side of the diodes. Looks to be fairly untouched so far. I also have the schematic. I have a pretty solid bunch of test equipment including a scope and generator etc...

How does R725 and R728 test at the base of Q706 and Q707 respectively ? In fact how do all the 1% resistors test out?

Be sure to test out the 5 tantalum electrolytic caps in the output stage, since you have checked the 8 volt regulators those can be passed over!

Noise and popping could be just a good old bad solder connection, have you pounded on that pc703 board yet, gave a good dance to all the components ?

NOTE that when you do voltage checks by the schematic that they are taken with no signal, no load and all controls full up!

Bill

Right on! Found voltages off on Q703 found a bad Tantalum (c707) dead short. I owe you a beer! Just gotta pick it up and I'll let you all know how I made out. oh almost forgot, r719 did look a little funny like it was drawing a lot of current!

Thanks

PS Boy am I glad I found this Forum.

There ya go!

couldn't have been anything too bad if it was not popping fuses, but now while it's out in the open you might want to replace all of those caps before another one goes south!

There is one cap right near the 5 watt resistor for Q705 and whenever I am in a amp I bend it as far clear of that 5 watt heat maker as I can to extend its life!

What revision number is your 703 board?

Steve

Thanks again, question, Q703 is marked 38735. Is this a NTE128? Can you explain to me what

this transistor does?
The board id marked "KEI-1 PC703"

steve probably missed your question. My list shows that a 36735 transistor is an RCA 40408, which is crossed to an NTE190.

Q703 is a voltage amp which boosts the signal from the input transistor and sends it on to the drivers.

Got a late start today, sorry!
What gives on the NTE site when I cross a 40408 I get a nte 16004 or nte16005?

Now i'm totally confused. The transistor in my PC703 is marked 38735 RCA I see no references to it on the parts list that is on this forum. The schematic that I have shows Q703 as a 38735. Chicago Bill may have made a mistake due to the fact he references " 36735 transistor is an RCA 40408"

Bottom line is i'm about to give up a replacement because the transistor "Q703" appears to be good anyway although the thought was in my case the shorted cap that I found (c709 tantalum 6.8ufd) stressed out the 2 470 ohm resistors and transistor q703 looked like it got real hot. The NTE190 that Bill references is a completely different casing. I guess I'll put the original back in when I get the cap and the 2 470ohm resistors.

Yes, that is a typo in my original list.

KEI part #007-0002-00 38735 RCA 40408

The current NTE cross reference gives the NTE16005 as a replacement.

[View Forum Message](#) <> [Reply to Message](#)

The problem is that the NTE190 shows a different case altogether.

[View Forum Message](#) <> [Reply to Message](#)

And the newer NTE16005 has a TO-39 case like the original. I'll have to look up an old NTE book to see what case the NTE190 had in the past.

NTE transistors are guaranteed to meet the electrical specs of the original transistors. Sometimes the cases and pinouts don't match the original ones. If the case has to fit a specific physical specification, then it won't work.

It's one of those shrunk down TO220 cases (more rectangular)with the thin metal tab on top.

Well, like I stated before I'm not going to replace Q703 since it checks ok on my meter. Just thought it would be a good idea to change it since it looked stressed.

I do want to thank you all for the quick responses. I wouldn't have fixed this without you folks.

Yeah, if it's good keep it in there!

I love helping folks out here on the board , all I ask in return is the winning power ball numbers! Lol!
